```

## SPARQL conjunctive queries

The core query language of SPARQL is: Basic Graph Pattern (BGP) queries, i.e. conjunctive or SELECT-PROJECT-JOIN queries.

### Example of a SPARQL conjunctive query

Return the names of scientists born in Europe who received a Nobel Prize

- ```
SELECT ?n WHERE { ?p rdf:type Scientist . ?p hasWon NobelPrize .
?p bornIn Europe . ?p hasName ?n . }
```
- ```
q(?n):- ?p rdf:type Scientist, ?p hasWon NobelPrize, ?p bornIn Europe, ?p
hasName ?n.
```

### A SPARQL query can search over the data and the schema

Return the properties having Europe as value

- ```
q(?prop):- ?s ?prop Europe.
```

# SPARQL evaluation over an RDF graph (by example)

$\theta(?prop)$  is an answer for each substitution  $\theta$  of the query variables by constants that maps every query conjunct to a fact.

## RDF graph G

```
wikipedia:Marie_Curie hasName "Marie Curie" .  
wikipedia:Marie_Curie rdf:type Chemist .  
wikipedia:Marie_Curie hasWonPrize NobelPrize.  
wikipedia:Marie_Curie bornIn Europe.  
wikipedia:Albert_Einstein hasName "Albert Einstein".  
wikipedia:Albert_Einstein rdf:type Physicist.  
wikipedia:Albert_Einstein hasWonPrize NobelPrize.  
wikipedia:Albert_Einstein birthPlace Ulm .  
Ulm locatedIn Germany. Germany partOf Europe.  
Chemist rdfs:subClassOf Scientist . Physicist rdfs:subClassOf Scientist .  
owl:ObjectPropertyChain (birthPlace Located partOf) rdfs:subPropertyOf bornIn.
```

```
q(?prop):- ?s ?prop Europe.
```

## Result of SPARQL evaluation over G

$q(G) = \{\text{bornIn , partOf}\}$

# SPARQL evaluation over an RDF graph (by example)

## RDF graph G

```
wikipedia:Marie_Curie hasName "Marie Curie" .  
wikipedia:Marie_Curie rdf:type Chemist.  
wikipedia:Marie_Curie hasWonPrize NobelPrize.  
wikipedia:Marie_Curie bornIn Europe.  
  
wikipedia:Albert_Einstein hasName "Albert Einstein".  
wikipedia:Albert_Einstein rdf:type Physicist.  
wikipedia:Albert_Einstein hasWonPrize NobelPrize.  
wikipedia:Albert_Einstein birthPlace Ulm .  
Ulm locatedIn Germany. Germany partOf Europe.  
  
Chemist rdfs:subClassOf Scientist . Physicist rdfs:subClassOf Scientist .
```

```
q(?n):?p rdf:type Scientist,?p hasWon NobelPrize,?p bornIn Europe,?p hasName ?n.
```

## Result of standard SPARQL evaluation over G

$q(G) = \emptyset$

# Query answering over RDF graphs requires reasoning

$G_{rdfs}^{\infty}$  : RDF facts + inferred facts by RDFS entailment

```
wikipedia:Marie_Curie hasName "Marie Curie" .  
wikipedia:Marie_Curie rdf:type Chemist.  
wikipedia:Marie_Curie hasWonPrize NobelPrize.  
wikipedia:Marie_Curie bornIn Europe.  
wikipedia:Albert_Einstein hasName "Albert Einstein".  
wikipedia:Albert_Einstein rdf:type Physicist.  
wikipedia:Albert_Einstein hasWonPrize NobelPrize.  
wikipedia:Albert_Einstein birthPlace Ulm .  
Ulm locatedIn Germany. Germany partOf Europe.  
Chemist rdfs:subClassOf Scientist . Physicist rdfs:subClassOf Scientist .  
wikipedia:Marie_Curie rdf:type Scientist.  
wikipedia:Albert_Einstein rdf:type Scientist.  
owl:ObjectPropertyChain (birthPlace Located partOf) rdfs:subPropertyOf bornIn.
```

```
q(?n):?p rdf:type Scientist,?p hasWon NobelPrize,?p bornIn Europe,?p hasName ?n
```

Query answer

$q(G_{rdfs}^{\infty}) = \{"\text{Marie Curie"}\}$

# Complete query answering may require full reasoning

$G^\infty$ : RDF facts + inferred facts by RDFS entailment + owl rules

```
wikipedia:Marie_Curie hasName "Marie Curie" .  
...  
wikipedia:Albert_Einstein hasName "Albert Einstein".  
wikipedia:Albert_Einstein rdf:type Physicist.  
wikipedia:Albert_Einstein hasWonPrize NobelPrize.  
wikipedia:Albert_Einstein birthPlace Ulm .  
Ulm locatedIn Germany . Germany partOf Europe.  
Physicist rdfs:subClassOf Scientist .  
wikipedia:Albert_Einstein rdf:type Scientist.  
owl:ObjectPropertyChain (birthPlace Located partOf) rdfs:subPropertyOf bornIn  
wikipedia:Albert_Einstein bornIn Europe
```

```
q(?n):?p rdf:type Scientist,?p hasWon NobelPrize,?p bornIn Europe,?p hasName ?n
```

Query answer

$q(G^\infty) = \{"\text{Marie Curie}", "\text{Albert Einstein}"\}$

# Challenges raised by query answering in Linked Data

## Scalability

- Linked Data cloud today: 9960 datasets, almost 150 billions triples (according to stats.lod2.eu)
  - Almost no support for reasoning and thus very incomplete answers
- ⇒ Need for efficient query answering techniques involving some reasoning

## Data quality

- Incomplete data (missing links, missing type information)
  - Noisy data (some hub datasets like DBpedia or Yago are automatically generated)
- ⇒ Need for robust query answering and information discovery techniques

## Remaining of the talk

A (partial) survey of recent works that have (partially) addressed some of these challenges using deductive RDF triplestores.

# Deductive RDF triplestore: RDF dataset + a set of rules

Simple formalism for capturing several types of knowledge

- RDFS entailment

$$(\exists \text{ rdf:type } ?s), (\exists s \text{ rdfs:subClassOf } ?o) \rightarrow (\exists i \text{ rdf:type } ?o)$$

- (Most of) OWL constraints

$$(\exists p \text{ birthPlace } ?b), (\exists b \text{ Located } ?c), (\exists c \text{ partOf } ?d) \rightarrow (\exists p \text{ bornIn } ?d)$$

- Beyond FOL constraints

$$(\exists p \text{ rdf:type } \text{owl:SymmetricProperty}), (\exists p \text{ rdfs:domain } ?c) \rightarrow (\exists p \text{ rdfs:range } ?c)$$

- (Complex) mappings

$$(\exists p1 \text{ ina:presenter } ?v), (\exists v \text{ ina:title } ?t), (\exists p2 \text{ db:presenter } ?t) \rightarrow (\exists p1 \text{ owl:sameAs } ?p2)$$

- Domain-specific rules (human embryo development)

$$(\exists x \text{ mycf:absence_implies } ?y), (\exists x \text{ mycf:depends_on } ?z) \rightarrow (\exists z \text{ mycf:absence_implies } ?x)$$

A Datalog operational semantics to compute  $G^\infty = \text{SAT}(D, R)$

- Direct correspondence with a deductive DB using a single relation T

$$(s \ p \ o) \leftrightarrow T(s \ p \ o)$$

## Several instances of this generic framework

My Corporis Fabrica: an ontology-based suite of tools for combining complex anatomical models

# My Corporis Fabrica and MyCF Embryo

Rule-based interoperability between anatomical entities, human body functions and 3D graphic models

⇒ a declarative approach assisting interactive simulation and visualization

IF( ?x rdf:type mcf:3D-object ) AND{ ?x mcf:Describes ?y }  
AND{ ?y rdf:type mcf:Muscle }  
THEN{ ?x mcf:hasColour 'yellow' } (R12)

**DATA**

This section shows a detailed semantic graph. At the top, **mcf:left\_sartorius** is connected to **mcf:Digital\_tendon\_of\_left\_sartorius** and **mcf:Proximal\_tendon\_of\_left\_sartorius** via **PartOf**. **mcf:Digital\_tendon\_of\_left\_sartorius** and **mcf:Proximal\_tendon\_of\_left\_sartorius** both **InsertOn** **mcf:Medial\_part\_of\_proximal\_syndesmosis\_left\_tibia**. **mcf:Medial\_part\_of\_proximal\_syndesmosis\_left\_tibia** **Contains** **mcf:id1**. **mcf:id1** **PartOf** **mcf:left\_tibia** and **mcf:left\_anterior\_superior\_left\_tibia**. **mcf:left\_tibia** **Contains** **mcf:id6**. **mcf:id6** **Contains** **mcf:3D\_object**. **mcf:3D\_object** **Displays** **mcf:left\_lower\_limb** and **mcf:3D\_scene**. **mcf:left\_lower\_limb** **Contains** **mcf:id7**. **mcf:3D\_scene** **Contains** **mcf:id5**. **mcf:id5** **Contains** **mcf:3D\_object**. **mcf:3D\_object** **Contains** **mcf:object\_1** and **mcf:object\_2**.

**QUERY**

Query in English:  
May I see, in the current 3D scene, the bones on which the left sartorius muscle is inserted?

Query in SPARQL:

```
PREFIX rdfs:<http://www.w3.org/2000/01/rdf-schema#>
PREFIX rdf:<http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX mcf:<http://www.mycorporisfabrica.org/ontology/mcf.owl#>

select ?bone ?individual ?mesh
where {?s mcf:InsertOn ?z.
?z mcf:PartOf ?y.
?y mcf:Contains ?bone.
?bone mcf:Contains ?individual.
?individual mcf:Type mcf:3D-object.
?individual mcf:hasMesh ?mesh}
```

**Answer**

| Bone                    | Individual     | Mesh                    |
|-------------------------|----------------|-------------------------|
| <b>mcf:left_tibia</b>   | <b>mcf:id6</b> | <b>..l_tibia.obj</b>    |
| <b>mcf:left_np_bone</b> | <b>mcf:id7</b> | <b>..l_hip_bone.obj</b> |

**3D view**

A 3D visualization showing the left hip joint and the left sartorius muscle. The left hip joint is labeled "Left hip bone (mcf:id7)". The left sartorius muscle is labeled "Left sartorius (mcf:id1)". An arrow points from the text "Left sartorius (mcf:id1)" to the muscle's representation in the 3D model.

Corresponding triples :

**mcf:Digital\_tendon\_of\_left\_sartorius mcf:insertsOn mcf:Medial\_part\_of\_proximal\_syndesmosis\_left\_tibia .**  
**mcf:Proximal\_tendon\_of\_left\_sartorius mcf:insertsOn mcf:Medial\_part\_of\_proximal\_syndesmosis\_left\_tibia .**  
**mcf:Medial\_part\_of\_proximal\_syndesmosis\_left\_tibia mcf:contains mcf:id1 .**  
**mcf:id1 mcf:partOf mcf:left\_tibia .**  
**mcf:left\_tibia mcf:contains mcf:id6 .**  
**mcf:id6 mcf:contains mcf:3D\_object .**  
**mcf:3D\_object mcf:displays mcf:left\_lower\_limb .**  
**mcf:left\_lower\_limb mcf:contains mcf:id7 .**  
**mcf:3D\_scene mcf:contains mcf:id5 .**  
**mcf:id5 mcf:contains mcf:3D\_object .**  
**mcf:3D\_object mcf:contains mcf:object\_1 .**  
**mcf:3D\_object mcf:contains mcf:object\_2 .**

# Module extraction from Semantic Web datasets

Reuse of relevant extracts of big reference Web knowledge bases  
⇒ a coherent and modular development of the Semantic Web

## Existing works

- Well studied for Description Logics
  - ▶ not applicable to RDF datasets (e.g, DBpedia, Yago)
  - ▶ generally untractable, tractable approximations
  - ▶ may output large modules: the whole Tbox in the worst case
- Little work for RDF databases
  - ▶ RDF subgraph extraction, traversal views
  - ▶ reasoning not considered

# Our contribution

## A novel semantics of modules adapted to deductive RDF datasets

- Module signature  $(p_1, \dots, p_n)^k[a]$  involving properties, and individual and a **bound k** for property paths rooted in the specified individual.
- $\langle D_M, R_M \rangle$  is a bounded-level module of  $\langle D, R \rangle$  iff  $D_M$  and  $R_M$  are conform to the signature,  $\langle D, R \rangle \vdash \langle D_M, R_M \rangle$ , and :

$$D, R^{\text{NonRec}} \vdash \pi_{(a,b)} \iff D_M, R_M \vdash \pi_{(a,b)} \quad (1)$$

$$D_M, R \vdash \pi_{(a,b)} \iff D_M, R_M \vdash \pi_{(a,b)} \quad (2)$$

for every path of atoms  $\pi_{(a,b)}$  of bounded length in the signature.

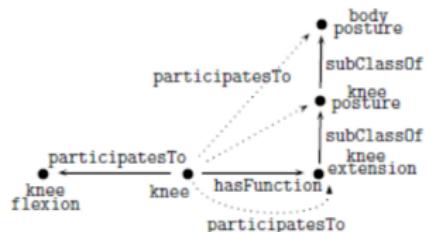

Non-recursive rules distinguished from recursive ones to avoid to waste k-parametricity.

## Algorithms for module extraction

- Module data extraction expressed as a **non-recursive Datalog program**
- Construction of the  $R_M$  module rules by **rule unfolding with a breadth-first strategy**

## Illustrative example

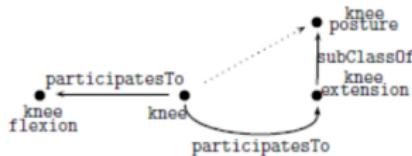

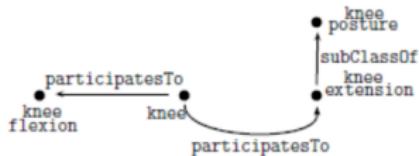

- Non recursive rules are needed to compute  $D_M$
- Recursive rules must be delegated to  $R_M$  (if they are conform to the signature)

$(x, \text{hasFunction}, y) \rightarrow (x, \text{ParticipatesTo}, y)$

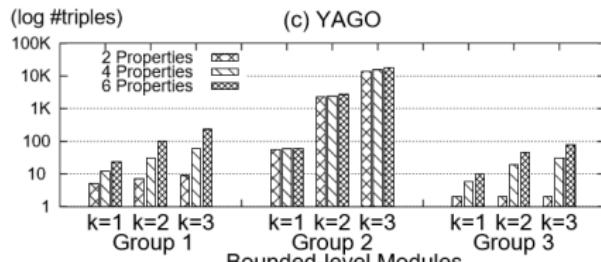

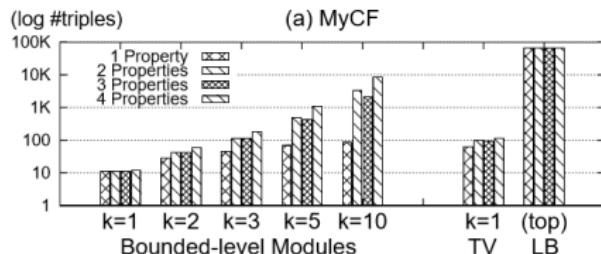

$(x, \text{ParticipatesTo}, y), (y, \text{subClassOf}, z)$   
 $\rightarrow (x, \text{ParticipatesTo}, z)$

[ $\text{participatesTo}$ ,  $\text{subClassOf}$ ]<sup>2</sup> (knee)      with the *delegated rule* ↓

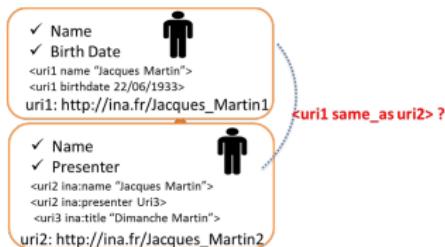

# Module succinctness: experiments

- ① Comparison on MyCF with Traversal Views (applied to the saturated RDF dataset) and Locality-based extractor (applied to the corresponding DL ontology)
- ② Impact of the properties in the signature: their number, their involvement and their interaction in (recursive) rules

# Rule-based data linkage

Within a local dataset or accross different datasets

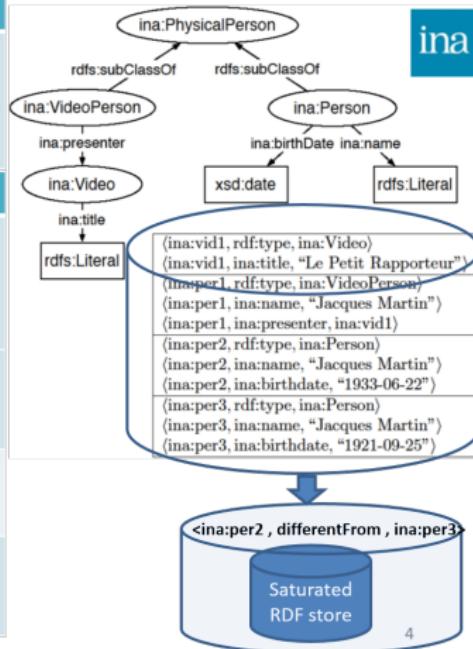

⇒ Our contributions:

- **Import-by-Query**, a backward-chaining algorithm combining local reasoning and external querying to bypass **local data incompleteness**
- **ProbFR**, a forward-chaining algorithm for reasoning with **uncertain data and rules**.

- ▷ joint work with M. Al Bakri, M. Atencia, J. David and Steffen Lalande (from INA)
- ▷ AAAI2015, ECAI2016

# Reasoning with local data may not be enough

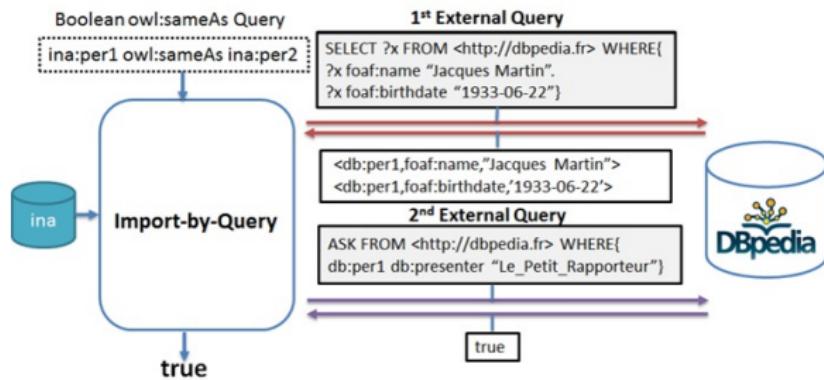

|    | IF                                                                                             | THEN                  |
|----|------------------------------------------------------------------------------------------------|-----------------------|
| R1 | ?p1 name ?name<br>?p1 birthdate ?d<br>?p2 name ?name<br>?p2 birthdate ?d                       | ?p1 same_as ?p2       |
| R2 | ?p1 name ?name<br>?p1 ina:presenter ?v1, ?v1 title ?t<br>?p2 name ?name<br>?p2 db:presenter ?t | ?p1 same_as ?p2       |
| R3 | ?p1 birthdate ?d1<br>?p2 birthdate ?d2<br>?d1 <> ?d2                                           | ?p1 differentFrom ?p2 |
| R4 | ?x1 same_as ?x2<br>?x2 same_as ?x3                                                             | ?x1 same_as ?x3       |
| R5 | ?x1 same_as ?x2<br>?x2 differentFrom ?x3                                                       | ?x1 differentFrom ?x3 |

BUT <ina:per1, same\_as, ina:per2> ? STILL UNKNOWN

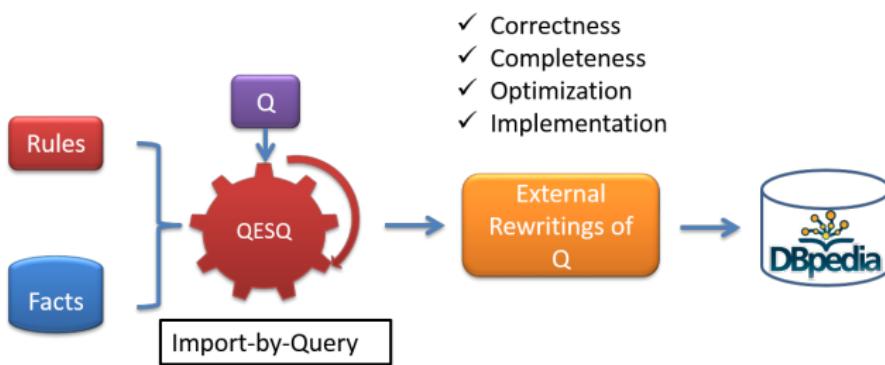

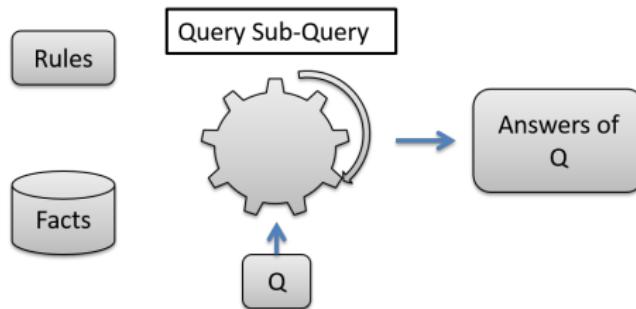

# Import-by-Query

- Build **on demand** queries to some entry points of Linked Data
- The queries should be **as instantiated as possible**.
- Alternates steps of **query rewriting** and of **distant query evaluation**

# Query rewriting by adapting Query-SubQuery

A backward-chaining algorithm developed for answering queries in Datalog

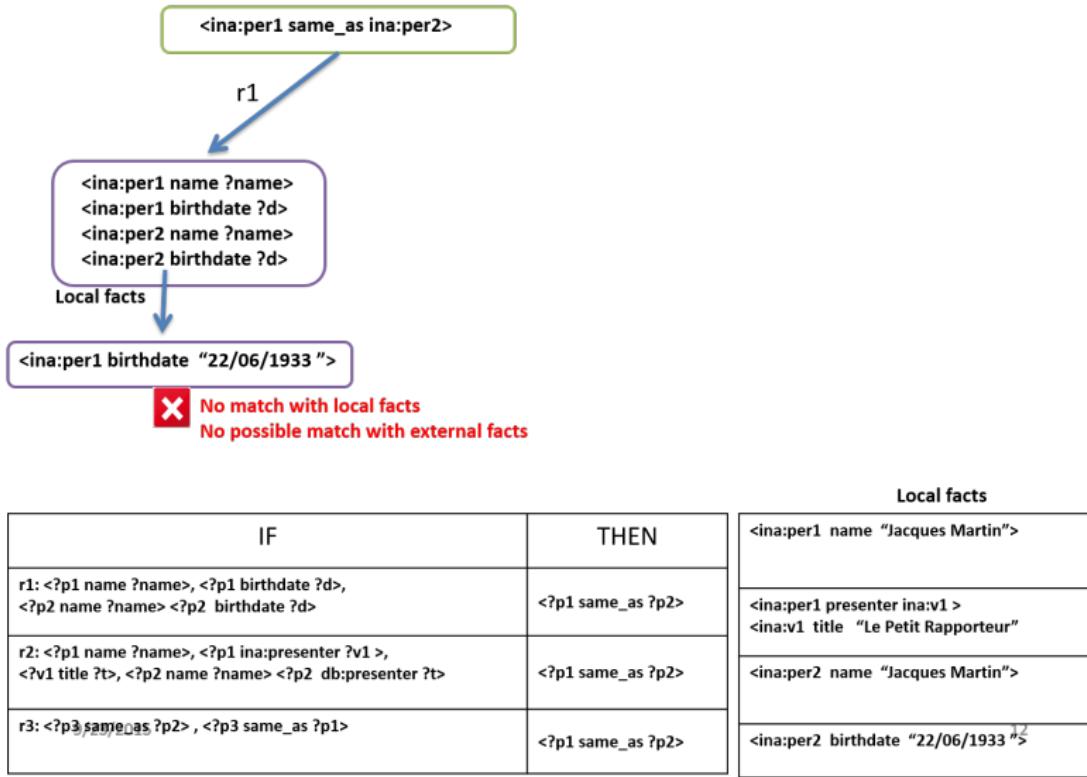

# Query rewriting (by example)

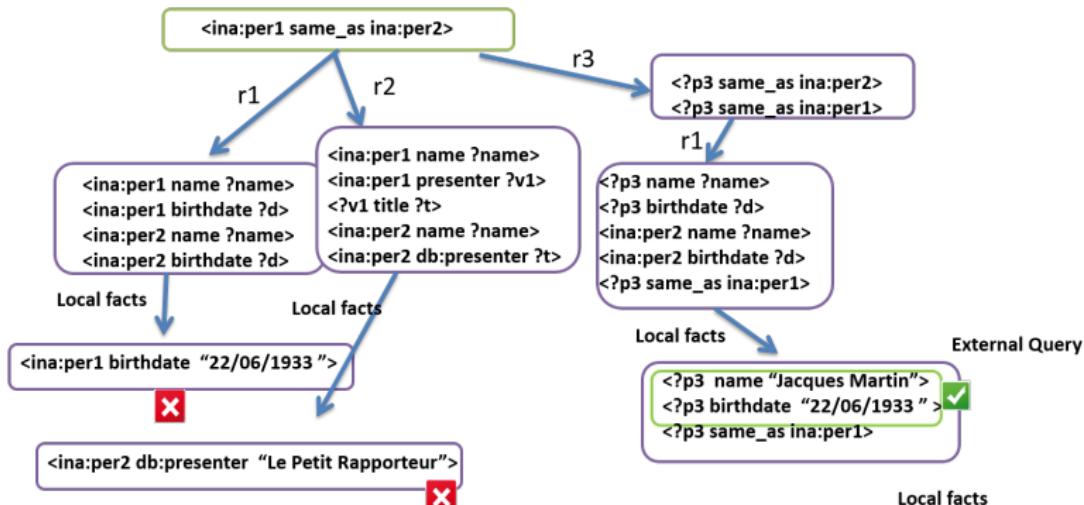

<ina:per1 same\_as ina:per2>

| IF                                                                                                    | THEN              |                                                                        |

# Results

- External information in Linked Data is useful for disambiguation

|                            | sameAs | DifferentFrom |
|----------------------------|--------|---------------|
| 35 rules<br>ina            | 2      | 10            |
| 35 rules<br>ina<br>Dbpedia | 4884   | 9764          |

- Full reasoning on (recursive) rules is useful
  - Comparison between Silk and a forward reasoner applied to our rules  
**Silk only discovered 3% of the sameAs links discovered by our approach**
  - 100% precision by construction (if the rules and the facts are correct)
    - checked in practice on a sample of 500 links
- Import-by-Query brings a drastic reduction of the imported facts

|                                                                 | Import By Query                       | Forward Reasoner |
|-----------------------------------------------------------------|---------------------------------------|------------------|
| Number of Imported Facts<br>for a sample of 500 Boolean queries | 6,417 facts<br>(13 per Boolean query) | 500,000 facts    |

- Import-by-Query requires 3 iterations of rewritings on average

|                                                                                                            |             |
|------------------------------------------------------------------------------------------------------------|-------------|
| Time to answer a boolean query <i>after</i> fact propagation                                               | 7 seconds   |
| Time to answer a boolean query <i>without</i> fact propagation                                             | 186 seconds |
| Time to propagate facts (done once for all queries)                                                        | 191 seconds |
| Gain of doing fact propagation beforehand for answering<br>the 500 reference queries using import-by-query | 96%         |

# ProbFR: Probabilistic Forward Reasoner

## Unifying modeling of any kind of uncertainty as probabilities

- noisy data (e.g., due to automatic data extraction from Wikipedia)
- pseudo-keys, constraints with exceptions
- weighted mappings between vocabularies across datasets

## Operational semantics of Probabilistic Datalog

- extension of probabilistic databases
- each input fact and rule is associated with a symbolic event
- an event expression is computed for each inferred fact, that encapsulates its provenance
- the probabilities are computed from the event expressions

## ProbFR implemented on top of JENA RETE

# Linkage between MusicBrainz and DBpedia using ProbFR

- MusicBrainz: 112 millions triples (12 GB)
- DBpedia (extract on songs, bands and persons): 73 millions triples
- 20 certain rules, 36 uncertain rules (probabilities from 0.3 to 0.9)
  - ▶ Runtime performance: less than 2 hours in total (including the loading time and the use of SOLR to compute some built-in predicates)
  - ▶ Impact of using uncertain information:
    - ★ Precision and recall based on certain rules only

|        | Precision | Recall |
|--------|-----------|--------|
| Person | 100%      | 8%     |
| Band   | 100%      | 12%    |

- ★ Precision and recall based on all the rules

|        | Precision | Recall |
|--------|-----------|--------|
| Person | 100%      | 80%    |
| Band   | 94%       | 84%    |
| Song   | 94%       | 74%    |

- ★ Precision and recall after filtering the inferred facts with a probability over a threshold

|                 | Precision | Recall |
|-----------------|-----------|--------|
| Band $\geq 0.9$ | 100%      | 80%    |
| Song $\geq 0.9$ | 100%      | 44%    |

# Conclusion

Semantic Web standards, data and applications are there

Linked Data is flourishing due to the simplicity and flexibility of the RDF data model.

However many challenges remain

- Efficient Semantic Web data and knowledge management is still challenging.
- Novel problems arise to handle at large scale the incomplete and uncertain nature of Web data

Our message:

(Extensions of) Datalog on top of RDF datasets is an interesting angle of attack for many of these challenges
